**Form and Function Background**

**Introduction**
Over time fish, as well as other animals, have adapted or changed to survive in their environment. Although different fish species have different appearances, the function of their outside body parts is similar. Moreover, the outside body parts (external anatomy features) of fish can tell us a lot about a species such as where it lives in the water, how it finds food, and how it protects itself from predators.

**External Anatomy Features**
Common external anatomy features of fish include: dorsal fin, anal fin, caudal fin, pectoral fins, ventral fins, gills, lateral line, nares, mouth, scales, and body shape.

**Fins**
All fish have external appendages called fins. Like human limbs, fins provide fish with balance, steering, and protection. Fins are either single along the centerline of the fish: the dorsal fin, anal fin, and tail fin; or paired fins: the pectoral fins and ventral fins.¹ Pectoral fins help fish balance. The top fin or dorsal fin is also used in balance but its main function is usually protection. The ventral fin and anal fin are located on the bottom or belly of fish and help with steering as well as balance. The tail fin, also called the caudal fin, helps propels fish forward.

**Gills**
Located on either side of fish, gills provide oxygen to fish from the water. The gills are covered by a flexible bony plate called the operculum. Some fish have spines located on the operculum as a defense mechanism to protect them from predators.²

**Lateral Line**
Running down the length of a fish’s body is the lateral line. This organ is used to feel low vibrations in the water. The lateral line is made up of a series of microscopic holes located just under the scales of a fish.³

**Nares**
All fish can smell. Located on a fish’s snout are paired holes, or nares used for detecting odors in the water. Some fish, like catfish and eels, have a heightened sense of smell.

**Scales and Slime**
Most fish have scales covering the length of their body. Scales protect fish from injury, much like skin on the human body. On top of these scales is a mucus covering known as the slime layer. Slime protects fish from bacteria and parasites in the water. Anglers should be careful not to remove the slime layer when handling a fish.⁴

**Body Shape**
A fish’s body shape as well as the shape and size of certain external features can tell you a lot about that fish. For example, the body shape of a fish can indicate where that fish lives in the water and what type of swimmer it is. In addition, tail fin shape also signifies a fish’s
swimming abilities. For instance, a sharp forked tail like that of a shark implies a fast swimmer, whereas a rounded tail means the fish is good at turning.

**Month**
The mouth parts of a fish will vary in size and may or may not contain teeth, depending on what the fish eats. The location of the mouth on a fish’s body can also give us a clue as to what the fish’s diet consists of. A superior mouth (a mouth pointing upward) means the fish will usually eat food located above it, whereas a fish with an inferior mouth (a mouth pointing downward) will usually eat food located below it.

**Form, Function, and Adaptations**
Although fish species may look very different from one another due to adaptations, their body parts serve similar functions. Here are a few examples:

**Fluke**
Fluke or summer flounder is a flat-lying saltwater fish that lives on the sea floor. When born, fluke look like any other fish, swimming upright. About a week to a month into its life, one eye rotates to the other side of the head to join the other eye. This adaptation allows fluke to lie flat on the ocean floor and wait for its food; thus it is called a lie-and-wait predator. Fluke also have many sharp teeth which allow it to eat smaller fish that swim above it. Although this fish looks different than most fish, the fins (caudal, pectoral, etc.) still have the same functions.

**Largemouth Bass**
Largemouth bass live towards the bottom of freshwater bodies and are therefore darker in color. Their greenish brown tint helps them to camouflage with the surrounding aquatic vegetation protecting them from predators swimming above. When swimming through the water, their white bellies help to camouflage them with the sky above. Largemouth bass have no teeth and can swallow their food whole. Adult largemouth can easily consume smaller fish, frogs, and even baby ducks. Although the mouth parts of largemouth bass are different than many other freshwater predators, they serve the same function: to consume food.

**Sea Robin**
Having several adaptations to protect it against predators, the sea robin is perhaps one of the most interesting fish. Because of its odd external characteristics, many humans consider the sea robin to be a trash fish, when in fact it is fine for human consumption. Sea robins are a bottom dwelling fish with very large pectoral fins. The large pectoral fins make the fish look larger to predators swimming through the water. As additional defense against predators, sea robins have a very sharp dorsal fin and spines on its gill covers. Sea robins can also make a quiet barking sound to scare off predators! Although the sea robin physically looks different than other species, its fins still help to balance its body, steer through the water, and protect it against predators.

**Relationship to Fishing**
Knowing what a fish eats, where it lives, and how it defends itself against predators can help us when fishing to target that species or to handle our catch. Depending on where a fish lives in the water changes how and where anglers fish for that species. For example, black sea bass prefer to live in and around structure, meaning rocks, dock pilings, etc. Therefore,
anglers targeting sea bass fish in these areas and in many cases go offshore to find reefs or wrecks to fish on. Similarly, catfish have a heightened sense of smell and lack superior vision. Therefore by knowing what the catfish eats, anglers can better target them by using baits with a strong odor, called stink baits.

Additional Resources

Vocabulary
- **Anal Fin**: Last bottom fin on a fish located near the anal opening; used in balance and steering
- **Caudal/Tail Fin**: Fin on end of fish; used to propel the fish
- **Dorsal Fin**: Top or backside fin on a fish; used for balance and protection
- **External Anatomy**: The outside body parts
- **Gills**: Organ a fish uses to obtain oxygen from the water
- **Lateral Line**: Organ a fish uses to “feel” low vibrations; tiny microscopic pores
- **Nares**: Organ a fish uses to smell; similar to nostrils
- **Pectoral Fin**: Chest fins on a fish; used for balance
- **Scales**: Protective cover on a fish; similar to skin
- **Slime**: Covers scales; layer protects from bacteria, parasites, etc.
- **Ventral Fin**: Bottom or belly fins on a fish; used in balance and steering
- **Vertebrate**: Organism with a backbone
